* Hhcycle variable is calculated using temporary variables. The final hhcycle variable is calculated from the variables q6 'Number of adults' and q7 + q8 (total number of children) 'Number of children'.

* Missing values are coded as 0 in order to include all variables and respondents in the calculations.

```
RECODE k5 to k9_10 (sysmis=0).

* Firstly, the number of children is calculated from the information on the number of children given by the respondent (q7 and q8).

```
COMPUTE child = k7 + k8 .
EXE .
```

- * Secondly, the number of children is calculated from the years of birth of children given by the respondent, that is, if any of the variables Q9_1 - qk9_10 contain a year of birth, the number of children is the number of years of birth given.

```
COUNT sv_child = k9_1 TO k9_10 (1 thru HI) .

- * If the respondent has supplied neither the number of children nor their years of birth (q7, q8, q9_1 - q9_10 = missing value or 0) but the total number of household members (q5) is higher than the number of adults (q6), the number of children is taken to be the difference between these two variables (q5 - q6).

<i>Note</i>	There are two weights available for calculations: 1) a weight that expands the results to the population level (the sum of the weights is the size of the population) (variable: WEIGHT) and 2) a weight that doesn't have the expansion property (the mean of the weights is 1 and the sum of the weights is the number of accepted responses, i.e. the size of the data) (variable: WEIGHT_2). Both of the weights are based on the same calibration process, only the scale differs.
